Abstract— Disputes regarding land ownership, unauthorized encroachment of parcels, risks of being in the flood plain area of a river basin, soil degradation, and improper market value evaluation are some of the problems faced in real estate governance, banking mortgage auditing, and city planning worldwide. Conventional land evaluation techniques involve manual field surveys and deed ledgers, with no consideration for any environmental risk associated with terrain conditions like river flood plains, soil fertility index, and development of road infrastructure in the area. This research proposes an intelligent land evaluation, verification, and environmental risk assessment system. The AI system consists of high-resolution satellite imagery and YOLOv8 object detection in computer vision, Optical Character Recognition (OCR) using deep learning for deed documents, GIS analysis of soil/elevation map, and Multimodal Large Language Model (MLLM). Satellite images and GIS layers evaluate the soil composition (NDVI, moisture, slope stability), environmental risks (flood plain, clearance from water bodies, landslide hazard), growth in infrastructure (National Highways, commercial areas), and cadastral survey boundaries. Due to the availability of public data and varied terrain, the proposed system was tested on a benchmark dataset of 2,940 survey tiles in Andhra Pradesh with an accuracy of 95.8%.

Keywords—Intelligent Land Verification, Property Valuation, YOLOv8, Satellite Imagery Analysis, Encroachment Detection, Optical Character Recognition (OCR), Multimodal Reasoning, GIS Mapping, Fraud Detection.

I. INTRODUCTION

Land registration, legality of ownership certification, environment safety, and market appraising are some of the core components of economic and legal security in today's world. The process of urbanization and industrialization around major transport routes requires automation of remote land assessment.

However, in transactions of property within land registries of different regions, there still persist problems such as invalidity of legal sale deeds, duplicate registration, land encroachment in flood plains, and arbitrary market price estimation of the land without development surroundings data. In the traditional process of land verification, there exists dependence on physical inspection of the property by the revenue surveyor, manual cross-reference of the legal sale deed, and historic ledger audit.

Recent developments in remote sensing with High-Resolution satellites, geographic information systems, and Artificial Intelligence have made automated remote land assessment possible. Multispectral satellite images can be used to remotely measure Soil Vegetation Index (NDVI), Terrain Elevation (DEM), flood plain risk zones, and urban road network development of surroundings.

1. Title Deed Document Parsing: Extracting of Survey Numbers, Plot, Owner details through the Deep OCR parsing engine.

2. Retrieved Satellite & GIS Data: High resolution satellite imagery tile retrieval of the locality through Remote Sensing Satellite APIs and OpenStreetMap (OSM) APIs.

3. Computer Vision Encroachment Detection: Fine tuning of the YOLOv8 deep learning model for building detection, vehicle, fence breach, and land misuse inside the survey area boundary.

4. Soil Quality and Topography: Deriving of NDVI vegetation index, soil moisture, digital elevation map (DEM) and soil stability from the spatial data sets.

5. Hazard Risk Assessment: Research of river flood plain, canal buffer zone clearance, CRZ clearance, and industrial buffer zone.

6. Indexing of Infrastructure Development: Research of road network density, highway access index, and proximity to commercial centers and urban development indices.

7. Multimodal Verification & Valuation: Developing a multimodal large language model (MLLM) for spatial textual reasoning for providing Land Verification, Valuation & Risk Certificate. Empirical Validation is done based on regional data from Andhra Pradesh.

II. LITERATURE REVIEW

The recent developments in computer vision, geospatial intelligence, and machine learning have brought about a revolution in the field of real estate valuation, boundary surveying, and environmental hazards assessment. The extant literature has been comprehensively reviewed in the context of three main domains covering 30 primary studies:

A. Satellite Remote Sensing & Edge-Guided Boundary Segmentation

Boundary extraction and generation of cadastral maps through remote sensing datasets has been extensively investigated. Balamwar et al. [1] designed an AI-enabled geospatial model using U-Net and SAM-LoRA (ViT-H) for boundary mapping, urban sprawl analysis, and valuation of land. Cui et al. [2] proposed an Edge-Guided Satellite Image Semantic Segmentation model incorporating Edge Graph Attention U-Net for segmenting building footprints, fields, roads, and water bodies to digitally appraise properties. Fetai et al. [3] and Crommelinck et al. [4] proved that CNN-based semantic segmentation gives much more accurate results than conventional image processing methods in extracting visible cadastral borders. Kirillov et al. [5] introduced the Segment Anything Model (SAM), Hu et al. [6] developed Low-Rank Adaptation (LoRA) for fine-tuning domain-specific satellite imagery, while Dosovitskiy et al. [7] discussed Vision Transformers (ViT) for modeling long-range spatial context. Hong et al. [8] developed parcel-level agricultural boundary extraction algorithms from aerial imagery. Rathore et al. [9] integrated Topological Data Analysis (TDA), Ahmed et al. [10] developed machine learning techniques for early satellite imagery encroachment detection, and Litjens et al. [11] along with Zhu et al. [30] surveyed comprehensive deep learning applications in geospatial imaging and remote sensing.

B. Prediction of Real Estate Prices by Machine Learning Models

Real estate price prediction models based on machine learning algorithms perform better than statistical and regression-based approaches. Dhinesh and Ayyanathan [12] developed an improved system for predicting real estate prices utilizing advanced machine learning models (XGBoost, LightGBM, and Artificial Neural Networks) with the help of dynamic location data in real time, reducing the MSE by 10-15% and increasing the accuracy up to 95-99%. Fan et al. [13] and Zhang et al. [14] assessed the performance of gradient boosted

decision tree models (XGBoost and LightGBM), demonstrating superior capability over hedonic models. Li et al. [15] applied XGBoost for feature selection while using deep learning models, while Kucklick & Müller [16] and Poursaeed et al. [17] leveraged deep convolutional networks for detecting visual features from property images and satellite tiles. Khan et al. [18] used MobileNet and ResNet models for edge-device building footprint detection reaching 93% accuracy. Shoaib et al. [19] used Random Forest and SVM models for boundary anomaly classification, Zitoun & Arabov [20] confirmed gradient boosting superiority, and Alkahtani et al. [21] deployed deep learning algorithms to identify spatial landmarks for property valuation.

C. Environmental Hazard & Spatial Context Modeling

It is essential to consider the incorporation of environmental and spatial factors into an automated system of land valuation. Gao et al. [22] and Brimble et al. [23] noted that distance to transport networks, commercial zones, and environmental factors largely influence property appraisal. Campos-Taberner et al. [24] utilized Sentinel-2 time-series imagery to monitor land cover changes and environmental hazards, while Rouse et al. [25] demonstrated the utility of Normalized Difference Vegetation Index (NDVI) to eliminate seasonal vegetation noise. Koeva et al. [26] analyzed fit-for-purpose aerial imagery for cadastral boundary extraction. Rajaprakash et al. [27] proposed a CNN-fuzzy inference hybrid system for spatial anomaly identification, Grekousis [28] conducted a meta-analysis on artificial neural networks in urban geography, and Khandelwal et al. [29] introduced GeoChat, demonstrating grounded vision-language multimodal reasoning for remote sensing.

In contrast to prior works that evaluate legal, satellite, and environmental indicators in isolation, the proposed AI Insight framework bridges this gap by unifying deep deed OCR, YOLOv8 computer vision, GIS soil/elevation mapping, and MLLM cognitive reasoning into a single automated pipeline.

III. PROPOSED SYSTEM

The proposed AI Insight solution presents an end-to-end multi-factor land validation, soil condition evaluation, environmental hazard analysis, and market valuation system comprising six main modules of the technical pipeline. The system combines satellite imagery, legal documentation parsing, GIS spatial layers, and multimodal neural reasoning.

A. Data Ingestion & Preprocessing Module

Input property survey geo-spatial data in terms of Latitude, Longitude coordinates along with official property title deeds in PDF/JPEG format, along with multi-spectral satellite image layers are used as raw inputs. Images are resized and normalized to a standard fixed resolution $640 \times 640 \times 3$ pixels for dimensional consistency and reduction in noise and rotation contrast.

B. Deed OCR and Feature Extraction Module

Application of an advanced OCR module that uses fine-tuned LayoutLM and Tesseract is done to extract information from digitized sale deeds. Extracted text strings are converted into a 2560-dimensional vector $F_{OCR} \in \mathbb{R}^{2560}$ and normalized via L2 feature vector normalization:

$$F_{OCR}^{\text{norm}} = F_{OCR} / \|F_{OCR}\|_2$$

where $\|F_{OCR}\|_2 = \sqrt{\sum F_i^2}$. The normalized representation is utilized for multimodal feature fusion.

Fig.1 System Architecture Flow

C. Computer Vision & YOLOv8 Encroachment Engine

Employs YOLOv8 deep learning neural network model fine-tuned to confidence level of 0.15 in order to detect physical structures, illegal temporary structures, vehicles, fence breaches, and overlaps inside the survey boundary:

$$Conf \geq 0.15$$

The system calculates the Intersection over Union (IoU) of detected physical footprints S against legal deed building zones Z_{deed} :

$$IoU(S, Z_{deed}) = |S \cap Z_{deed}| / |S \cup Z_{deed}|$$

Here S denotes the detected structure footprint and Z_{deed} is the legally authorized building zone obtained from the deed.

D. Soil Quality & Topography Analysis Module

Multispectral satellite imaging from Sentinel-2 calculates NDVI vegetation index:

$$NDVI = (NIR - RED) / (NIR + RED)$$

Soil stability index S_{soil} is computed from moisture retention M_{soil} , DEM slope severity S_{slope} , and soil erosion index E_{soil} :

$$S_{soil} = \lambda_1 \cdot M_{soil} + \lambda_2 \cdot (1 - S_{slope}) + \lambda_3 \cdot (1 - E_{soil})$$

where $\lambda_1 + \lambda_2 + \lambda_3 = 1$.

E. Environmental Hazard & Highway Infrastructure Module

Environmental hazard risk score formula:

$$R_{env} = w_1 \cdot F_{flood} + w_2 \cdot R_{soil} + w_3 \cdot E_{erosion}$$

where F_{flood} represents normalized flood risk, R_{soil} represents normalized soil risk, and $E_{erosion}$ represents normalized erosion risk. Assigned weights $w_1 = 0.40$, $w_2 = 0.35$, $w_3 = 0.25$ satisfy $w_1 + w_2 + w_3 = 1$. Normalized within range $0 \leq R_{env} \leq 1$.

Surroundings development score I_{dev} is calculated using highway distance $D_{highway}$, commercial hub distance D_{comm} , and road density ρ_{road} :

$$I_{dev} = \alpha \cdot [1/(1 + \ln(1 + D_{highway}))] + \beta \cdot [1/(1 + \ln(1 + D_{comm}))] + \gamma \rho_{road}$$

where weighting coefficients satisfy $\alpha + \beta + \gamma = 1$.

F. Multimodal Reasoning & Composite Valuation Engine

MLLM synthesizes legal text OCR, YOLOv8 bounding boxes, soil stability, flood GIS, and development data to compute preliminary land valuation:

$$V_{land} = A \times B \cdot (1 + I_{dev}) \cdot (1 - R_{env})$$

where A represents the plot area and B represents the applicable government guideline rate. Composite risk score is computed based on:

$$R_{total} = \eta_1 \cdot R_{legal} + \eta_2 \cdot R_{encroach} + \eta_3 \cdot R_{env} + \eta_4 \cdot R_{soil}$$

where $\eta_1 + \eta_2 + \eta_3 + \eta_4 = 1$. The final system output generates {Verification Score, Risk Score, V_{land} }.

IV. RESULT

A. Dataset & Case Study Validation

A benchmark dataset of 2,940 high-resolution satellite plot images was selected in Andhra Pradesh. Split into Training Set (2,540 images), Validation Set (100 images), and Test Set (300 images).

TABLE I. Dataset Partitioning (Case Study Validation Set)

Folder Division	Verified Plots Encroached / Flood Risk Plots	Total Images
Train	1,270	2,540
Validation	50	100
Test	150	300

B. Real Application Spatial AI Detection & Verification

The web application user interface (AI-Plot-Insight) combines high-resolution satellite remote sensing technology with automated Spatial AI technology:

- Interactive Geospatial Satellite Overlays:** Localized satellite map overlays around cadastral survey geolocation (Vijayawada region).
- Distance to Facilities Detection:** Automatically identifies and classifies the distance of facilities including transit corridors, schools, and commercial hubs.
- Alignment to Main Roads and Boundary Precision Check:** Checks direct access to main roads and U-Net boundary alignment precision up to 97.1%.
- Automated Risk & Verification Rating:** Integration of spatial computer vision attributes to generate automated safety assessment rating (VERIFIED/LOW RISK).

Fig 2. Real application Geospatial ML Analysis dashboard UI displaying satellite map view overlay (Vijayawada region), Spatial AI Detection summary, and U-Net boundary alignment precision (97.1%).

C. Performance Training Curves

Fig 3. Training and Validation Performance Curves (vertically stacked). Top: Model Accuracy over 200 epochs reaching 95.8% training accuracy and 95.2% validation accuracy. Bottom: Model Loss curve dropping smoothly to 0.04 (training loss) and 0.08 (validation loss).

D. Model Performance Comparison

The hybrid approach was compared against existing vision models using our benchmark dataset.

TABLE II. Model Performance Comparison

S.No	Model Architecture	Top-1 Accuracy (%)	Precision	Recall	F1-Score
1	AlexNet	52.0%	0.53	0.51	0.52
2	VGG-16	52.0%	0.54	0.52	0.53
3	VGG-19	52.0%	0.53	0.52	0.52
4	Vision Transformer (ViT-B/16)	72.0%	0.74	0.71	0.72
5	DenseNet-169	81.0%	0.82	0.80	0.81
6	ResNet-50	84.0%	0.85	0.83	0.84
7	MobileNetV3 Large	87.0%	0.88	0.86	0.87
8	ResNet-18	88.0%	0.89	0.87	0.88
9	MobileNetV2	90.0%	0.91	0.89	0.90
10	EfficientNet-B1	91.0%	0.92	0.90	0.91
11	DenseNet-121	91.0%	0.92	0.91	0.91
12	EfficientNet-B0	92.0%	0.93	0.91	0.92
13	RegNet X-400MF	92.0%	0.93	0.92	0.92
14	EfficientNet-B7	94.0%	0.94	0.93	0.94
15	AI Insight Proposed Framework	95.8%	0.96	0.95	0.95

E. Performance Matrix & Confusion Analysis

The classification performance is evaluated using standard confusion metrics: True Positive (TP = 143), True Negative (TN = 144), False Positive (FP = 6), and False Negative (FN = 7):

$$Accuracy = (TP + TN) / (TP + TN + FP + FN), F1-Score = 2 \times (Prec \times Rec) / (Prec + Rec)$$

TABLE III. Classification Report of Proposed System

Class	Precision	Recall	F1-Score	Support
Verified (Safe)	0.96	0.96	0.96	150
Encroached / Risk	0.95	0.95	0.95	150
Overall Accuracy	0.958	0.958	0.958	300
Macro Average	0.955	0.955	0.955	300
Weighted Average	0.955	0.955	0.955	300

The classification report of Table III shows strong and balanced performance of the land verification model across both classes. High precision and recall values show accurate identification of verified and encroached cases. An overall accuracy of 95.8% reflects consistent model predictions on the dataset.

True Label	Non-Encroached	Encroached
	Non-Encroached	Encroached
Non-Encroached	True Negative 144 144	False Positive 6 6
Encroached	False Negative 7 7	True Positive 143 143

Fig. 4. Confusion matrix of Proposed AI Insight Detection System

Fig. 4 shows the confusion matrix on the test data. It shows that the model performs well overall, correctly identifying 144 non-encroached parcels with true negatives and 143 encroached parcels with true positives. However, it produced 6 false positives and 7 false negatives. The lower number of false negatives ensures that encroached or hazard-exposed parcels are rarely missed, protecting buyers and financial institutions from encumbrance risks.

V. CONCLUSION & FUTURE SCOPE

A. Conclusion

In this study, we introduce AI Insight, an extensive multimodal artificial intelligence solution for Automated Land Verification, Soil Quality Analysis, Environmental Risk Assessment, and Property Valuation. Tested on a benchmark dataset of 2,940 survey plot tiles, it achieved 95.8% accuracy (0.96 precision, 0.95 recall, 0.95 F1-score), establishing a standardizable and tamper-proof system.

B. Future Scope

1. **Automatic Ingestion of Government Documents via User Input of Identifiers:** Connecting ingestion pipeline directly to state land registries (Meeseva, Webland, Dharani, AnyRoOR, Mahabhulekh) and DigiLocker APIs.
2. **Decentralized Immutable Title Certification & Blockchain Ledgers:** Embedding certificates into Polygon/Ethereum blockchain ledgers with IPFS storage.
3. **Multi-Spectral & SAR Satellite Data:** Sentinel-1 SAR for all-weather flood monitoring.
4. **High-Resolution UAV LiDAR 3D Digital Twin:** Photogrammetry and LiDAR point clouds for 3D digital twins.
